(57) **ABSTRACT**

Methods, systems, and computer program products for providing transaction verification through enhanced authentication are provided. A method performed by a computer system may include receiving one or more credentials to authenticate an application programming interface request received from a second computer system based on a first level of authentication, generating an additional authentication challenge to further authenticate the application programming interface request in response to detecting a change associated with the second computer system, issuing the additional authentication challenge to the second computer system, and processing the application programming interface request based on a result of the additional authentication challenge.

In some examples, the additional authentication challenge may be encrypted using a key associated with the second computer system before issuance of the additional authentication challenge. For example, the key may be a public key corresponding to a private key stored in a highly secure area on the second computer system.

## TRANSACTION VERIFICATION THROUGH ENHANCED AUTHENTICATION

### TECHNICAL FIELD

The present invention generally relates to computer system security and, more particularly, to verification of computer-initiated transactional requests using enhanced authentication.

### BACKGROUND

An application programming interface (API) generally refers to a set of one or more functions, procedures, components, and services provided by a software library or a computer system. Web APIs allow clients to consume API services offered by another computer system over the internet. However, web APIs can be vulnerable to various types of cyber-attacks.

For example, a takeover of a client computer system can provide an attacker with credentials and unlimited access to web APIs accessible from a compromised client. In addition, a man-in-the-middle attacker may intercept and use web API authentication credentials to access private information, credit card accounts, bank accounts, or other secure data by impersonating a client.

Highly restrictive security measures may offer increased web API security. However, such measures can disrupt the flow of legitimate traffic and transactions. Accordingly, improved methods of authentication can provide better protection against takeover, man-in-the-middle, and other types of cyber-attacks while flexibly accepting routine changes occurring on a computer system or network without disrupting legitimate activity.

### BRIEF DESCRIPTION OF THE DRAWINGS

Various examples of the present disclosure will be understood more fully from the detailed description given below and from the accompanying drawings of various examples of the disclosure. In the drawings, like reference numbers may indicate identical or functionally similar elements. The drawing in which an element first appears is generally indicated by the left-most digit in the corresponding reference number.

FIG. 1 is a block diagram illustrating a system architecture, in accordance with various examples of the present disclosure.

FIG. 2 is a flow diagram illustrating transaction verification using enhanced authentication, according to an example of the present disclosure.

FIG. 3 is a flow diagram illustrating transaction verification using enhanced authentication with encryption, according to an example of the present disclosure.

FIG. 4 is a block diagram of an exemplary computer system that may perform one or more of the operations described herein.

### DETAILED DESCRIPTION

Systems, methods, and computer program products for verifying transactions using enhanced authentication are disclosed.

In an example, a client computer system seeks to use an application programming interface (API) provided by a server computer system. The server receives a key from the

2

client for encrypting one or more additional authentication challenges to be issued to the client beyond a first level of authentication.

In an example, a client may provide the key to the server at a time of initial account registration and setup, at a subsequent time as part of an account or registration update, when the account associated with the client exceeds a transaction volume threshold, when the account or sales of the account associated with the client exceeds a monetary value threshold, when it is determined that data handled by the account associated with the client is classified as sensitive, based on a request from the server, or at any other time or based on any other criteria.

In an example, the client sends a request to use a server-provided API. The client also provides one or more authentication credentials to allow the server to authenticate the client's API request based on a first level of authentication.

In an example, the server authenticates the API request, analyzes information associated with the client (e.g., identity, location, behavior, etc.), and detects that one or more attributes of the client have changed. In response, the server generates an additional authentication challenge to further authenticate the API request received from the client. In one example, the server encrypts the additional authentication challenge using the key received from the client and sends the encrypted additional authentication challenge to the client.

In an example, the client receives the encrypted additional authentication challenge. In one example, the key for decrypting the encrypted additional authentication challenge is stored in a highly secure area owned by an administrator or other privileged account of the client computer system. The client escalates the encrypted additional authentication challenge to the privileged account having access to the decryption key in the highly secure area. The privileged account then returns the decrypted additional authentication challenge for further processing.

In an example, the server receives a response to the encrypted additional authentication challenge from the client. The server then analyzes the response, determines whether a result of the additional authentication challenge was successful or unsuccessful, and processes the API request received from the client based on the result.

Accordingly, aspects of the present disclosure provide improved security of application programming interfaces (APIs) to protect against server takeovers and man-in-the-middle attacks while allowing administrative and other legitimate changes to be made without incident.

FIG. 1 illustrates an exemplary system architecture **100** in which examples of the present disclosure may be implemented. System architecture **100** includes a server machine **110**, a data store **180** and client machines **102A-102N** connected to a network **104**. Network **104** may be a public network (e.g., the Internet), a private network (e.g., a local area network (LAN) or wide area network (WAN)), or a combination thereof. In an example, network **104** may include the Internet and/or one or more intranets, wired networks, wireless networks, and/or other appropriate types of communication networks. In one example, the network **104** may comprise a wireless telecommunications network (e.g., cellular phone network) adapted to communicate with other communication networks, such as the Internet.

Data store **180** is persistent storage that is capable of storing various types of data, such as text, audio, video and image content. In some examples data store **180** might be a network-attached file server, while in other examples data store **180** might be some other type of persistent storage such as an object-oriented database, a relational database, and so forth.

Client machines **102A-102N** may be personal computers (PC), laptops, mobile phones, tablet computers, server computers, wearable computing devices, or any other computing devices. Client machines **102A-102N** may run an operating system (OS) that manages hardware and software of the client machines **102A-102N**. A browser (not shown) may run on the client machines (e.g., on the OS of the client machines). The browser may be a web browser that can access content and services provided by a web server **120** of server machine **110**. Other types of computer programs and computer scripts also may run on client machines **102A-102N**.

Client machines **102A-102N** each may include a web server **104A**, **104N** and a secure area **106A**, **106N** used to store keys **108A**, **108N**. Web servers **104A**, **104N** may include web and/or application servers configured to utilize one or more application programming interfaces (APIs) provided by server machine **110**. An API generally refers to an interface provided for utilizing functionality of software components or other software-based services available from a computer system or software library.

APIs may include any software-based API, such as operating system APIs, programming language APIs, web-based APIs, web services (SOAP, REST, etc.), public APIs, private APIs, proprietary APIs, mobile APIs, transactional APIs, etc. In some examples, use of APIs provided by server machine **110** may be secured and/or tied to user accounts of clients **102A-102N**. Thus, a client **102A** may provide one or more authentication credentials (e.g., a user name and/or password) to server machine **110** to use an API exposed by server machine **110**.

In an example, client machines **102A-102N** use an API provided by server machine **110** to initiate and complete various types of transactions. For example, client machines **102A-102N** may use one or more server machine **110** APIs to purchase goods, sell goods, transfer money, make payments, perform various financial transactions, etc. Client machines **102A-102N** may be associated with the same organization or may include computer systems that are operated by different organizations. For example, client machines **102A-102N** may be comprised of computer systems of unrelated organizations that each have contracted to utilize services provided from an API on server machine **110**.

Clients **102A-102N** each may include a corresponding secure area **106A-106N** used to store a respective key **108A-108N** and other secure data. A secure area **106A-106N** generally refers to any area on a computer system that is separate and inaccessible to a web server, application server, computer program or process used to call server machine **110** APIs. For example, a secure area **106A** may be a storage area owned by a root account, an administrative user, or another user. In some examples, data access to a secure area **106A** requires privilege escalation or assistance from a user or account authorized to access the secure area **106A** (e.g., root, administrator, etc.).

Keys **108A-108N** generally refer to one or more pieces of information that determine the functional output of a cryptographic algorithm or cipher. For example, a key **108A** may be used to encrypt and/or decrypt various types of data and may include symmetric keys, asymmetric keys, hash functions, or any other data that may be used to encrypt or decrypt data. A key **108A** may be associated with one or more computer systems of a client **102A**. In an example, a key **108A** may be associated with a single client **102A** computer system or associated with multiple clients **102A-102N**.

Server machine **110** may be a rackmount server, a router computer, a personal computer, a portable digital assistant, a mobile phone, a laptop computer, a tablet computer, a camera,

a video camera, a netbook, a desktop computer, a media center, or any combination thereof. Server machine **110** may include a web server **120** and a transaction authentication system **130**. In some examples, web server **120** and transaction authentication system **130** may run on one or more different machines.

Web server **120** may provide text, audio, and video images from data store **180** to clients **102A-102N**. Web server **120** also may provide web-based application services and business logic to clients **102A-102N**. Clients **102A-102N** may locate, access and consume various forms of content and services from web server **120** using applications, such as a web browser, web servers, application servers, computer programs, etc. Web server **120** also may receive text, audio, video and image content from clients **102A-102N** that is saved in data store **180** for purposes that may include preservation and distribution of content. Further, web server **120** may receive API requests from various clients **102A-102N**.

In an example, web server **120** is coupled to one or more applications servers (not shown) that provide applications, services, and transactional APIs to clients **102A-102N**. For example, web server **120** may provide clients **102A-102N** with access to one or more application services, which include but are not limited to banking, electronic commerce, e-mail, social networking, etc. Such functionality also may be provided, for example, as one or more different web applications, standalone applications, systems, plugins, web browser extensions, and application programming interfaces (APIs). In some examples, plugins and extensions may be referred to, individually or collectively, as add-ons.

In an example, some clients **102A-102N** may include applications associated with a service provided by server **110**. In one example, one or more device types (e.g., smart phones, smart televisions, tablet computers, etc.) may use applications to access content provided by server **110**, to issue commands to server **110**, and/or to receive content from server **110** without visiting or using web pages.

In an example, functions performed by server **110** and/or web server **120** also may be performed by the client machines **102A-102N**, in whole or in part. In addition, the functionality attributed to a particular component may be performed by different or multiple components operating together. Server **110** also may be accessed as a service provided to other systems or devices via appropriate application programming interfaces, and thus is not limited to use with websites.

In an example, transaction authentication system **130** includes an API request receiver module **140**, an API security manager module **150**, and an API request processor module **160**. In other examples, functionality associated with API request receiver module **140**, API security manager module **150**, and API request processor module **160** may be combined, divided and organized in various arrangements.

In an example, API request receiver module **140** receives API requests sent to server machine **110** by clients **102A-102N**. For example, API request receiver module **140** may receive API requests sent from a client **102A** to a web or application server running on server machine **110**. API request receiver module **140** also may receive one or more API credentials from a client **102A**, for example, to authenticate use of a secure API by the client.

In an example, API security manager module **150** receives keys for performing additional authentication of server machine **110** API requests. For example, API security manager module **150** may receive a respective key from each of one or more clients **102A-102N**. In one example, API security manager module **150** receives a key from a client **102A**, associates the received key with the client **102A**, and stores

5

the received key for encrypting one or more additional authentication challenges to be issued to the client 102A.

In an example, a client 102A provides an encryption key to server machine 110 at a time of initial account registration and setup, at a subsequent time as part of an account or registration update, when the account associated with the client 102A exceeds a transaction volume threshold, when the account or sales of the account associated with the client 102A exceeds a monetary value threshold, when it is determined that data handled by the account associated with the client 102A is classified as sensitive, based on a request from the server, or at any other time or based on any other criteria.

In an example, API security manager module 150 associates a client-provided key with a specific client 102A or multiple clients 102A-102N during a registration process where one or more clients 102A-102N are configured to access a secure API provided by server machine 110. In one example, API security manager module 150 identifies and stores information about one or more clients 102A-102N associated with a client-provided key. For example, API security manager module 150 may collect identifying information about each of one or more clients 102A-102N (e.g., machine name, IP address, MAC address, domain, network information, network paths, etc.). Such information may include attributes unique to a client 102A and other general information known about the client (e.g., typical transaction periods, frequency, amounts, etc.). API security manager module 150 may store such information for each of one or more clients 102A-102N in corresponding client profiles.

In an example, API security manager 150 compares identifying information known about a client 102A to new corresponding information gathered, collected or received from a client 102A at another time. For example, API security manager module 150 may compare identifying information known about a client 102A to information associated with or gathered at the time an API interface request is received from the client 102A.

In an example, API security manager module 150 detects a change associated with the client 102A based on one or more of identification information associated with a client 102A, network information associated with a client 102A, usage of a server machine 110 API by a client 102A, transactional attributes of an API request received from a client 102A, etc. For example, API security manager module 150 may generate one or more additional authentication challenges to issue to a client 102A in response to detecting one or more changes associated with identity and/or behavior of the client 102A.

Additional authentication challenges generally refer to a second or extra level of authentication performed by API security manager module 150 to further authenticate a client 102A beyond first-level authentication. In some examples, API security manager module 150 may generate and issue one or more additional authentication challenges to a client 102A randomly, in view of a detected change associated with a client 102A, based on a client 102A request (e.g., during client 102A registration or testing), when a client 102A exhibits suspicious behavior deviating from an observed pattern of past client 102A behavior, in addition to first-level authentication to further authenticate a server machine 110 API request received from a client 102A, etc. In some examples, a first-level authentication challenge may ask a client 102A to provide one or more credentials, such as a username, password, PIN, passphrase, etc.

In an example, an additional authentication challenge may request that a client 102A solve one or more mathematical calculations, answer one or more questions, or perform one or more tasks. In one example, API security manager module

6

150 issues an additional authentication challenge to a client 102A requesting that the client 102A perform the task of obtaining a resource (e.g., a file) from a particular computer system or network location.

In an example, API security manager module 150 issues an additional authentication challenge involving one or more mathematical problems. For example, API security manager module 150 may ask a client 102A to solve a mathematical problem that is numeric, an equation, a puzzle, or a mathematical problem described in words. In one example, API security manager module 150 asks a client 102A to provide a plurality of answers for a mathematical problem having at least two correct answers (e.g., correct positive and negative answers, etc.).

In an example, API security manager module 150 encrypts an additional authentication challenge generated for a client 102A with a key that has been associated with the client 102A. In one example, API security manager module 150 encrypts an additional authentication challenge with a client 102A associated key prior to issuing the additional authentication challenge to the client 102A. For example, API security manager module 150 may encrypt the additional authentication challenge using a key previously received from the client 102A during a registration process to utilize a server machine 110 API.

In an example, a client 102A provided key received by API security manager module 150 may be used to perform one of symmetric or asymmetric encryption/decryption between server machine 110 and a client 102A. In one example, a key 108A provided to API security manager module 150 by a client 102A may be used both to encrypt and decrypt an additional authentication challenge. In another example, a client may provide a key to API security manager module 150 for encrypting an additional authentication challenge that the client 102A later decrypts using a corresponding, but different key 108A. For example, client 102A may provide API security manager module 150 with a public key for encrypting data that client 102A decrypts using a private key 108A stored in a highly secure area 106A owned by an administrative user account.

In an example, API security manager module 150 issues an additional authentication challenge to a client 102A and waits for a response. In one example, a client 102A receives an encrypted additional authentication challenge issued from API security manager module 150. For example, a web server 104A, application server, or other computer program running on client 102A may receive an encrypted additional authentication challenge from API security manager module 150. The web server 104A, application server, or other computer program running on client 102A then may escalate the encrypted additional authentication challenge to a privileged user account or process having access to a secure area 106A holding a key 108A for decrypting the encrypted additional authentication challenge. The elevated user or process then may decrypt the additional authentication challenge and return the result to the calling web server 104A, application server, or other computer program of client 102A. Client 102A then may process the additional authentication challenge and return a corresponding response to API security manager module 150 for evaluation.

In an example, API security manager module 150 waits for a period of time after issuing an additional authentication challenge to allow a client 102A to receive, process, and respond to the additional authentication challenge. In one example, API security manager module 150 allows a client 102A to respond to an issued additional authentication challenge before a timeout occurs based on a threshold. Further,

when API security manager module **150** does not receive a response from a client **102A** before a timeout occurs, then a new additional authentication challenge may be issued, an issued additional authentication challenge may be reissued, or the issued authentication challenge may be deemed unsuccessful without further attempt.

In an example, API security manager module **150** receives a response to an issued additional authentication challenge from client **102A**, analyzes the response to the additional authentication challenge received from the client **102A**, and determines whether the response to the additional authentication challenge is correct or acceptable. In one example, API security manager module **150** then provides a result of the additional authentication challenge to API request processor module **160** based on the determination. For example, API security manager module **150** may indicate whether the additional authentication challenge issued to a client **102A** was successful or unsuccessful.

In an example, API request processor module **160** performs one or more activities based on a result of the additional authentication challenge. For example, API request processor module **160** may execute a server machine **110** API request received from a client **102A** based on a successful result of an additional authentication challenge. API request processor module **160** also may deny a server machine **110** API request from a client **102A** when an incorrect response is received or no response is provided for an additional authentication challenge.

In an example, API request processor module **160** blocks one or more pending or subsequent server machine **110** API requests from a client **102A** associated with an unsuccessful additional authentication challenge. API request processor module **160** also may block one or more pending or subsequent server machine **110** API requests from clients **102A-102N** related to another client associated with an unsuccessful additional authentication challenge. For example, multiple clients **102A-102N** associated with a user account or associated with a party that contracted to use a server machine **110** API may be blocked under such circumstances.

In an example, API request processor module **160** sends a notification to a user associated with a client **102A** account, a server **110** account, or a contracted party when an unsuccessful additional authentication challenge occurs and/or a security adjustment is made in response to an unsuccessful additional authentication challenge. For example, API request processor module **160** may notify an account holder by sending an e-mail, initiating a call, sending a text message, etc. In some examples, API request processor module **160** adjusts a risk model associated with one or more clients **102A-102N** or accounts based on results of additional authentication challenges.

FIG. 2 is a flow diagram illustrating transaction verification using enhanced authentication, according to an example of the present disclosure. The method **200** may be performed by processing logic that may comprise hardware (circuitry, dedicated logic, programmable logic, microcode, etc.), software (such as instructions run on a general purpose computer system, dedicated machine, or processing device), firmware, or a combination thereof.

Method **200** begins at block **202** when an API request receiver module **140** of a transaction authentication system **130** receives one or more credentials to authenticate an application programming interface (API) request received from a second computer system based on a first level of authentication. In an example, API request receiver module **140** receives one or more credentials to authenticate a server machine **110** API request from a client **102A**. For example, a client may be

prompted or use an available API to provide one or more of a username, password, PIN, passphrase, etc. to satisfy a first-level of authentication associated with a server machine API. In one example, API request receiver module **140** receives client **102A** credentials with an API request from the client **102A**. Such credentials may be provided by a client **102A**, for example, once at the beginning of a session, one or more times throughout a session, or generally any number of times.

At block **204**, an API security manager module **150** of a transaction authentication system **130** issues an additional authentication challenge to the second computer system to further authenticate the application programming interface request. In an example, API security manager module **150** generates an additional authentication challenge to further authenticate a server machine **110** API request from a client **102A** beyond a standard first-level of authentication. For example, API security manager module **150** may generate an additional authentication challenge that is issued to a client **102A** requesting access to or use of a server machine **110** API.

In an example, API security manager module **150** generates and issues an additional authentication challenge to a client **102A** in response to detecting a change associated with the client **102A**. For example, API security manager module **150** may detect an identity change, a network change, a behavioral change, suspicious transactional behavior, or another change associated with a client **102A**. In response, API security manager module **150** may generate and issue one or more additional authentication challenges to the respective client **102A** associated with the detected change.

In an example, API security manager module **150** receives a response to an additional authentication challenge from a client **102A**. API security manager module **150** then analyzes the response to the additional authentication challenge to determine whether the response is correct or incorrect. In some examples, a client **102A** provides an encrypted response to the additional authentication challenge, for example using SSL, to preserve data privacy and to protect the data from unauthorized interception. In one example, API security manager module **150** provides a result of the additional authentication challenge to API request processor module **160** based on the determination. For example, the result provided by API security manager module **150** may indicate whether the additional authentication challenge was successful or unsuccessful.

At block **206**, an API request processor module **160** of a transaction authentication system **130** processes the application programming interface request received based on a result of the additional authentication challenge. In an example, API request processor module **160** of a server machine **110** API executes a request received from a client **102A** based on a successful additional authentication challenge result. In an example, API request processor module **160** denies a server machine **110** API request from a client **102A** based on an unsuccessful additional authentication challenge result.

In an example, API request processor module **160** blocks one or more pending and/or subsequent server machine **110** API requests from a client **102A** based on an unsuccessful additional authentication challenge result. In one example, API request processor module **160** blocks one or more pending and/or subsequent server machine **110** API requests from a group of clients **102A-102N** associated with one or more unsuccessful additional authentication challenges. For example, a group of two or more clients **102A-102N** associated with an account or party that contracted to use a server machine **110** API may be blocked in response to an unsuccessful authentication challenge result for one client **102A**.

In an example, API request processor module **160** notifies one or more of a user, a client account holder, or a server machine **110** API owner in response to one or more unsuccessful additional authentication challenges (e.g., a single unsuccessful result, a number of consecutive unsuccessful results, a proportion of unsuccessful results in a sampling of results that exceeds a predefined threshold, etc.). For example, API request processor module **160** may send an e-mail, initiate a call, send a text message, etc. API request processor module **160** also may adjust a risk model associated with one or more clients **102A-102N** based on a result of an additional authentication challenge. For example, a client **102A** trust level may increase in response to a successful result and may decrease in response to an unsuccessful result.

FIG. 3 is a flow diagram illustrating transaction verification using enhanced authentication with encryption, according to an example of the present disclosure. The method **300** may be performed by processing logic that may comprise hardware (circuitry, dedicated logic, programmable logic, microcode, etc.), software (such as instructions run on a general purpose computer system, dedicated machine, or processing device), firmware, or a combination thereof.

Method **300** begins at block **302** when an API security manager module **150** of a transaction authentication system **130** receives a key for encrypting one or more additional authentication challenges to be issued to a second computer system. In an example, API security manager module **150** receives a key for encrypting additional authentication challenges to be issued to a client **102A**. For example, API security manager **150** may receive the key from client **102A** as part of a registration process where client **102A** is configured to access server machine **110** APIs. In one example, API security manager **150** receives a public key from a PGP key pair for encrypting additional authentication challenges to be issued to client **102A**. The public key corresponds to a private key **108A** stored in a secure area **106A** of the client **102A** and is used for decrypting additional authentication challenges by a privileged client **102A** account having access to the secure area **106A**.

At block **304**, an API request receiver module **140** of a transaction authentication system **130** receives an application programming interface request from the second computer system. In an example, API request receiver module **140** receives a server machine **110** API request from a client **102A**. For example, a client **102A** may send an API request to server machine **110** to call an API providing banking, electronic commerce, e-mail, social networking, or another service.

At block **306**, The API request receiver module **140** receives one or more credentials to authenticate the application programming interface request based on a first level of authentication. In an example, API request receiver module **140** receives one or more first-level authentication credentials from a client **102A** seeking to access a server machine **110** API. First-level authentication credentials may include any combination of a username, password, PIN, passphrase, etc. In one example, API request receiver module **140** receives one or more first-level authentication credentials with an API request. In another example, API request receiver module **140** receives first-level authentication credentials in a client **102A** communication separately from an API request.

At block **308**, API security manager module **150** detects a change associated with the second computer system. In an example, API security manager module **150** collects and stores information about one or more clients **102A-102N**. For example, API security manager module **150** may gather identifying or other information about each of one or more clients

**102A-102N** (e.g., machine name, IP address, MAC address, domain, network information, network paths, etc.). Such information may include attributes unique to a client **102A** and other general information known about a client **102A** (e.g., typical transaction periods, frequency, amounts, etc.). In one example, API security manager module **150** stores such information for each of one or more clients **102A-102N** in respective client profiles.

In an example, API security manager **150** compares information known about a client **102A** to new corresponding information gathered, collected or received from the client **102A** at another time. For example, API security manager module **150** may compare identifying information known about a client **102A** to information associated with an API interface request received from the client **102A**. In one example, API security manager module **150** detects a change associated with the client **102A** based on one or more of client **102A** identification information, client **102A** network information, usual client **102A** behavior, transactional attributes of an API request, frequency of client **102A** API requests, etc.

At block **310**, API security manager module **150** generates an additional authentication challenge to further authenticate the application programming interface request. In an example, API security manager module **150** generates an additional authentication challenge in response to detecting one or more changes associated with the identity or behavior of a client **102A**.

In an example, an additional authentication challenge generated by API security manager module **150** may include one or more mathematical calculations, one or more fact-based, predetermined or secret questions, or one or more tasks. In one example, API security manager module **150** generates an additional authentication asking a client **102A** to perform a task of obtaining a resource (e.g., a file, data) from a location.

At block **312**, API security manager module **150** issues the additional authentication challenge to the second computer system. In an example, API security manager module **150** issues an additional authentication challenge to a client **102A** to further authenticate the identity of the client **102A** beyond first-level authentication. For example, API security manager module **150** may issue the additional authentication challenge to a client **102A** in response to detecting a change associated with the client **102A**. In some examples, API security manager module **150** identifies an identity change, a network change, a behavioral change, suspicious transactional attributes or behavior, or other observed difference associated with a client **102A**.

In an example, API security manager module **150** later receives a response to the additional authentication challenge from a client **102A** and analyzes the response to determine a result. API security manager module **150** then may provide a result of the additional authentication challenge to API request processor module **160** based on the determination. For example, the result provided by API security manager module **150** may indicate whether a client **102A** provided a correct or an incorrect response to the additional authentication challenge.

At block **314** an API request processor module **160** processes the application programming interface request based on a result of the additional authentication challenge. In an API request processor module **160** of a transaction authentication system **130** processes an API request received from a client **102A** based on a result of an additional authentication challenge. In an example, API request processor module **160** of a server machine **110** API executes a server machine **110** API request based on a successful result. In another example,

11

API request processor module **160** denies a server machine **110** API request based on an unsuccessful result.

In an example, API request processor module **160** notifies one or more users, account holders, or other parties when an additional authentication challenge is unsuccessful. For example, API request processor module **160** may provide notification by sending an e-mail, initiating a call, sending a text message, etc. In one example, API request processor module **160** adjusts a risk model associated with one or more clients **102A-102N** based on a result of an additional authentication challenge. For example, a client **102A** trust level may increase in response to a successful result and may decrease in response to an unsuccessful result.

FIG. 4 illustrates a diagram of a machine in the exemplary form of a computer system **400** within which a set of instructions, for causing the machine to perform any one or more of the methodologies discussed herein, may be executed. In other examples, the machine may be connected (e.g., networked) to other machines in a LAN, an intranet, an extranet, or the Internet. The machine may operate in the capacity of a server or a client machine in client-server network environment, or as a peer machine in a peer-to-peer (or distributed) network environment. The machine may be a personal computer (PC), a tablet PC, a set-top box (STB), a Personal Digital Assistant (PDA), a cellular telephone, a web appliance, a server, a network router, switch or bridge, or any machine capable of executing a set of instructions (sequential or otherwise) that specify actions to be taken by that machine. Further, while only a single machine is illustrated, the term “machine” shall also be taken to include any collection of machines that individually or jointly execute a set (or multiple sets) of instructions to perform any one or more of the methodologies discussed herein.

The exemplary computer system **400** includes a processing device (processor) **402**, a main memory **404** (e.g., read-only memory (ROM), flash memory, dynamic random access memory (DRAM) such as synchronous DRAM (SDRAM), double data rate (DDR SDRAM), or DRAM (RDRAM), etc.), a static memory **406** (e.g., flash memory, static random access memory (SRAM), etc.), and a data storage device **418**, which communicate with each other via a bus **430**.

Processor **402** represents one or more general-purpose processing devices such as a microprocessor, central processing unit, or the like. More particularly, the processor **402** may be a complex instruction set computing (CISC) microprocessor, reduced instruction set computing (RISC) microprocessor, very long instruction word (VLIW) microprocessor, or a processor implementing other instruction sets or processors implementing a combination of instruction sets. The processor **402** may also be one or more special-purpose processing devices such as an application specific integrated circuit (ASIC), a field programmable gate array (FPGA), a digital signal processor (DSP), network processor, or the like. The processor **402** is configured to execute instructions **422** for performing the operations and steps discussed herein.

The computer system **400** may further include a network interface device **408**. The computer system **400** also may include a video display unit **410** (e.g., a liquid crystal display (LCD) or a cathode ray tube (CRT)), an alphanumeric input device **412** (e.g., a keyboard), a cursor control device **414** (e.g., a mouse), and a signal generation device **416** (e.g., a speaker).

The data storage device **418** may include a computer-readable storage medium **428** on which is stored one or more sets of instructions **422** (e.g., software) embodying any one or more of the methodologies or functions described herein. The instructions **422** may also reside, completely or at least par-

12

tially, within the main memory **404** and/or within the processor **402** during execution thereof by the computer system **400**, the main memory **404** and the processor **402** also constituting computer-readable storage media. The instructions **422** may further be transmitted or received over a network **420** via the network interface device **408**.

In one example, the instructions **422** include instructions for one or more modules of a transaction authentication system (e.g., transaction authentication system **130** of FIG. 1) and/or a software library containing methods that call a transaction authentication system **130**. While the computer-readable storage medium **428** (machine-readable storage medium) is shown in an example to be a single medium, the term “computer-readable storage medium” should be taken to include a single medium or multiple media (e.g., a centralized or distributed database, and/or associated caches and servers) that store the one or more sets of instructions. The term “computer-readable storage medium” shall also be taken to include any medium that is capable of storing, encoding or carrying a set of instructions for execution by the machine and that cause the machine to perform any one or more of the methodologies of the present disclosure. The term “computer-readable storage medium” shall accordingly be taken to include, but not be limited to, solid-state memories, optical media, and magnetic media.

In the foregoing description, numerous details are set forth. It will be apparent, however, to one of ordinary skill in the art having the benefit of this disclosure, that the present disclosure may be practiced without these specific details. In some instances, well-known structures and devices are shown in block diagram form, rather than in detail, in order to avoid obscuring the present disclosure.

Some portions of the detailed description have been presented in terms of algorithms and symbolic representations of operations on data bits within a computer memory. An algorithm is here, and generally, conceived to be a self-consistent sequence of steps leading to a desired result. The steps are those requiring physical manipulations of physical quantities. Usually, though not necessarily, these quantities take the form of electrical or magnetic signals capable of being stored, transferred, combined, compared, and otherwise manipulated. It has proven convenient at times, for reasons of common usage, to refer to these signals as bits, values, elements, symbols, characters, terms, numbers, or the like.

It should be borne in mind, however, that all of these and similar terms are to be associated with the appropriate physical quantities and are merely convenient labels applied to these quantities. Unless specifically stated otherwise as apparent from the following discussion, it is appreciated that throughout the description, discussions utilizing terms such as “computing”, “comparing”, “applying”, “transmitting”, “receiving”, “processing,” or the like, refer to the actions and processes of a computer system, or similar electronic computing device, that manipulates and transforms data represented as physical (e.g., electronic) quantities within the computer system’s registers and memories into other data similarly represented as physical quantities within the computer system memories or registers or other such information storage, transmission or display devices.

Certain examples of the present disclosure also relate to an apparatus for performing the operations herein. This apparatus may be constructed for the intended purposes, or it may comprise a general-purpose computer selectively activated or reconfigured by a computer program stored in the computer. Such a computer program may be stored in a computer readable storage medium, such as, but not limited to, any type of disk including floppy disks, optical disks, CD-ROMs, and

## 13

magnetic-optical disks, read-only memories (ROMs), random access memories (RAMs), EPROMs, EEPROMs, magnetic or optical cards, or any type of media suitable for storing electronic instructions.

It is to be understood that the above description is intended to be illustrative, and not restrictive. Many other examples will be apparent to those of skill in the art upon reading and understanding the above description. The scope of the disclosure should, therefore, be determined with reference to the appended claims, along with the full scope of equivalents to which such claims are entitled.

What is claimed is:

1. A computer system, comprising:
  - a non-transitory memory storing instructions; and
  - one or more hardware processors coupled to the non-transitory memory and configured to read the instructions from the non-transitory memory to cause the system to perform operations comprising:
    - receiving, by a computer system providing access to an application programming interface, a public key provided by a user for encrypting an additional authentication challenge, the public key being provided by the user in advance of a request to use the application programming interface from a client device claiming to be associated with the user;
    - receiving, by the computer system, one or more credentials to authenticate the application programming interface request from the client device based on a first level of authentication;
    - encrypting, by the computer system, the additional authentication challenge that is to be issued to the client device requesting access to the application programming interface using the public key provided in advance by the user;
    - issuing the encrypted additional authentication challenge to the client device to further authenticate the application programming interface request based on detecting that information known about the user differs from information associated with the client device;
    - processing the application programming interface request based on a result of issuing the encrypted additional authentication challenge to the client device; and
    - detecting, by the computer system, abnormal use of the application programming interface associated with the client device based on a deviation from baseline usage of the application programming interface.
2. The computer system of claim 1, wherein the operations further comprise:
  - receiving, by the computer system, the application programming interface request from the client device.
3. The computer system of claim 1, wherein the operations further comprise:
  - detecting, by the computer system, a difference between information known about the user and information associated with the client device.
4. The computer system of claim 1, wherein the operations further comprise:
  - detecting, by the computer system, an identity attribute change for the user based on information associated with the client device.
5. The computer system of claim 1, wherein the operations further comprise:
  - detecting, by the computer system, a network attribute change for the user based on information associated with the client device.

## 14

6. The computer system of claim 1, wherein the abnormal use is detected based on a deviation from an observed baseline pattern of application programming interface activity associated with the user.

7. The computer system of claim 1, wherein the operations further comprise:

- generating, by the computer system, the additional authentication challenge to further authenticate the application programming interface request in response to detecting that information known about the user differs from information associated with the client device.

8. The computer system of claim 1, wherein the operations further comprise:

- associating, by the computer system, the public key for encrypting the additional authentication challenge with an account associated with the user.

9. The computer system of claim 1, wherein the public key received by the computer system corresponds to a private key stored in a secure area on the client device.

10. The computer system of claim 1, wherein the operations further comprise:

- permitting, by the computer system, the application programming interface request when a correct response to the additional authentication challenge is received from the client device.

11. The computer system of claim 1, wherein the operations further comprise:

- denying, by the computer system, the application programming interface request when an incorrect response to the additional authentication challenge is received from the client device.

12. The computer system of claim 1, wherein the operations further comprise:

- denying, by the computer system, the application programming interface request when a period of time expires before receiving a response to the additional authentication challenge.

13. The computer system of claim 1, wherein the operations further comprise:

- blocking, by the computer system, one or more subsequent application programming interface requests from the client device based on failure of the client device to provide an acceptable response to the additional authentication challenge.

14. The computer system of claim 1, wherein the user provides the public key for encrypting the additional authentication challenge to prevent an unauthorized party having access to the credentials from using the application programming interface.

15. The computer system of claim 1, wherein the user provides the public key from a secure location associated with a privileged account of the user.

16. The computer system of claim 1, wherein the public key is associated with a corresponding private key for decryption, the private key being stored in a secure area accessible to a privileged account associated with the user.

17. A computer-implemented method, comprising:

- receiving, by one or more processor devices, a public key from a user for encrypting an additional authentication challenge, the public key being provided by the user in advance of a request to use a web-based application programming interface from a client device claiming to be associated with the user;

- receiving, by the processor devices, one or more credentials to authenticate the web-based application programming interface request from the client device based on a first level of authentication;

15

encrypting, by the processor devices, the additional authentication challenge to further authenticate the web-based application programming interface request using the public key provided in advance by the user;

issuing, by the processor devices, the encrypted additional authentication challenge to the client device based on detecting that information known about the user differs from information associated with the client device;

processing, by the processor devices, the web-based application programming interface request based on a result of issuing the encrypted additional authentication challenge to the client device; and

detecting, by the processor devices, abnormal use of the application programming interface associated with the client device based on a deviation from baseline usage of the application programming interface.

18. The computer-implemented method of claim 17, further comprising:

receiving, by the processor devices, the web-based application programming interface request from the client device.

19. The computer-implemented method of claim 17, further comprising:

detecting, by the processor devices, a difference between information known about the user and information associated with the client device.

20. The computer-implemented method of claim 17, further comprising:

detecting, by the processor devices, an identity attribute change for the user based on information associated with the client device.

21. The computer-implemented method of claim 17, further comprising:

detecting, by the processor devices, a network attribute change for the user based on information associated with the client device.

22. The computer-implemented method of claim 17, wherein the abnormal use is detected based on a deviation from an observed baseline pattern of application programming interface activity associated with the user.

23. The computer-implemented method of claim 17, further comprising:

generating, by the processor devices, the additional authentication challenge to further authenticate the web-based application programming interface request in response to detecting that information known about the user differs from information associated with the client device.

24. The computer-implemented method of claim 17, further comprising:

associating, by the processor devices, the public key for encrypting the additional authentication challenge with an account associated with the user.

25. The computer-implemented method of claim 17, wherein the public key received by the computer system corresponds to a private key stored in a secure area on the client device.

26. The computer-implemented method of claim 17, further comprising:

permitting, by the processor devices, the web-based application programming interface request when a correct response to the additional authentication challenge is received from the client device.

27. The computer-implemented method of claim 17, further comprising:

denying, by the processor devices, the web-based application programming interface request when an incorrect

16

response to the additional authentication challenge is received from the client device.

28. The computer-implemented method of claim 17, further comprising:

denying, by the processor devices, the web-based application programming interface request when a period of time expires before receiving a response to the additional authentication challenge.

29. The computer-implemented method of claim 17, further comprising:

blocking, by the processor devices, one or more subsequent application programming interface requests from the client device based on failure of the client device to provide an acceptable response to the additional authentication challenge.

30. The computer-implemented method of claim 17, wherein the user provides the public key for encrypting the additional authentication challenge to prevent an unauthorized party having access to the credentials from using the web-based application programming interface.

31. The computer-implemented method of claim 17, wherein the user provides the public key from a secure location associated with a privileged account of the user.

32. The computer-implemented method of claim 17, wherein the public key is associated with a corresponding private key for decryption, the private key being stored in a secure area accessible to a privileged account associated with the user.

33. A non-transitory machine-readable medium having stored thereon machine-readable instructions executable to cause a machine to perform operations comprising:

receiving a request to use an application programming interface from a client device claiming to be associated with a registered user of the application programming interface;

generating the additional authentication challenge to further authenticate the request to use the application programming interface based on detecting that information known about the user differs from information associated with the client device;

encrypting the additional authentication challenge using the public key provided by the user;

processing the application programming interface request based on a result of issuing the encrypted additional authentication challenge to the client device; and

detecting abnormal use of the application programming interface associated with the client device based on a deviation from baseline usage of the application programming interface.

34. The non-transitory machine-readable medium of claim 33, further comprising:

receiving the application programming interface request from the client device.

35. The non-transitory machine-readable medium of claim 33, further comprising:

detecting a difference between information known about the user and information associated with the client device.

36. The non-transitory machine-readable medium of claim 33, further comprising:

detecting an identity attribute change for the user based on information associated with the client device.

37. The non-transitory machine-readable medium of claim 33, further comprising:

detecting a network attribute change for the user based on information associated with the client device.

17

38. The non-transitory machine-readable medium of claim 33, wherein the abnormal use is detected based on a deviation from an observed baseline pattern of application programming interface activity associated with the user.

39. The non-transitory machine-readable medium of claim 33, further comprising:

generating the additional authentication challenge to further authenticate the application programming interface request in response to detecting that information known about the user differs from information associated with the client device.

40. The non-transitory machine-readable medium of claim 33, further comprising:

associating the public key for encrypting the additional authentication challenge with an account associated with the user.

41. The non-transitory machine-readable medium of claim 33, wherein the public key received by the computer system corresponds to a private key stored in a secure area on the client device.

42. The non-transitory machine-readable medium of claim 33, further comprising:

permitting the application programming interface request when a correct response to the additional authentication challenge is received from the client device.

43. The non-transitory machine-readable medium of claim 33, further comprising:

18

denying the application programming interface request when an incorrect response to the additional authentication challenge is received from the client device.

44. The non-transitory machine-readable medium of claim 33, further comprising:

denying the application programming interface request when a period of time expires before receiving a response to the additional authentication challenge.

45. The non-transitory machine-readable medium of claim 33, further comprising:

blocking one or more subsequent application programming interface requests from the client device based on failure of the client device to provide an acceptable response to the additional authentication challenge.

46. The non-transitory machine-readable medium of claim 33, wherein the user provides the public key for encrypting the additional authentication challenge to prevent an unauthorized party having access to the credentials from using the application programming interface.

47. The non-transitory machine-readable medium of claim 33, wherein the user provides the public key from a secure location associated with a privileged account of the user.

48. The non-transitory machine-readable medium of claim 33, wherein the public key is associated with a corresponding private key for decryption, the private key being stored in a secure area accessible to a privileged account associated with the user.
